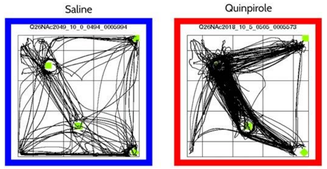
Introduction

Motivation
The management, exploration, and visualization of behavioral neuroscience data is hindered by isolated data silos, rigid schema constraints, and ad-hoc analysis tools. Modern behavioral research generates large-scale datasets spanning thousands of experimental sessions, with complex, multidimensional relationships between subjects, surgical manipulations, pharmaceutical treatments, and granular behavioral observations.

The Problem:
Traditional methods of data management (such as scattered spreadsheets and isolated SPSS files) are cumbersome, error-prone, and severely limit a researcher's ability to cross-reference data or perform longitudinal studies efficiently.



Objective

Deliver a secure platform that enables seamless multi-source data ingestion, natural language querying, and dynamic visualization, accelerating progress in OCD behavioral research.

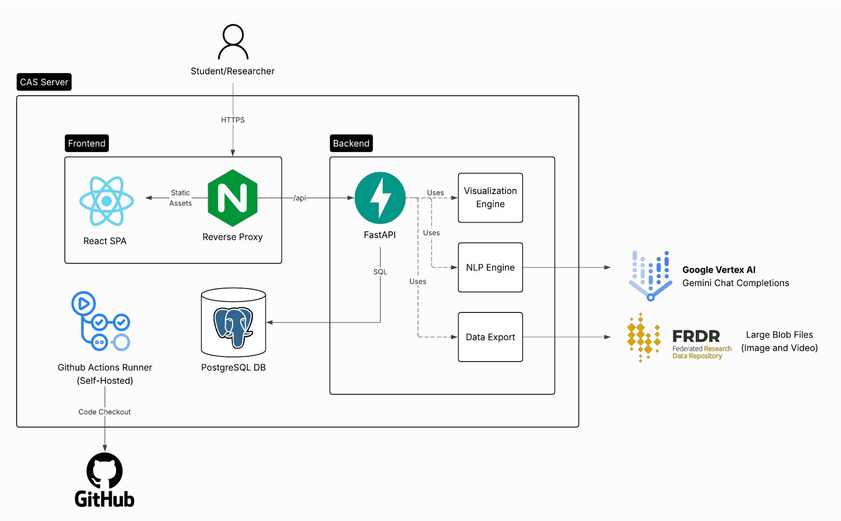
Centralized Data Hub: Provide a robust relational database capable of supporting session-centric neurobehavioral data schemas to serve data for students and researchers alike. Leverage session filter output to provide a unified hub for downloading otherwise fragmented experimental files.

Extensible Analytics Platform: Offer dynamic data exploratory capabilities through a robust, configurable Visualization Engine of compulsive checking criteria. Allow for session-based visualizations for evaluating the size of datasets based on parameters such a drug injection. Provide analytical tools to evaluate single sessions including a path plot trajectory and various summary measures.

Artificial Intelligence Enabled Insights: Provide access for non-technical students and researchers to perform granular, fine-tuned queries on the available data powered by an LLM pipeline which transforms natural language into robust SQL queries, expanding the possibilities of experimental design with the available dataset.

Engineering Overview

Architecture Diagram:



Tech Stack:

- *Python*
- *TypeScript*
- *Nginx*
- *Docker*
- *Google Vertex AI (or Local)*
- *PostgreSQL*

Results

Natural Language Querying Interface: Researchers can query the database conversationally without SQL knowledge, using Ask mode for autonomous execution or Select mode to review the generated SQL, with matched session files available for instant download.

Dynamic Data Visualization Engine: The platform offers Bar Charts, Line Charts, Heatmaps, and a Behavior Graph Dashboard that consolidates five key queries into a unified multi-panel view for rapid behavioral exploration.

Filterable Data Inventory: A Data Inventory view displays raw file counts across the dataset, filterable by drug treatment, file type, drug regimen, brain manipulation, and apparatus, with a toggle to isolate unoperated subjects.

Analysis ToolBox: Researchers can load any rat session by ID to inspect its full tracked data points and Path Trajectory map for session-level behavioural analysis.
